

Expenses and Savings Tracker

This project is a simple console-based application in Python to track monthly expenses and savings. It provides a detailed yearly summary and offers additional functionalities such as:

- Viewing yearly expenses and savings
- Calculating savings over multiple years with interest
- Displaying the percentage breakdown of expenses

How It Works

1. Collecting User Inputs

```
print("Enter your monthly income:")
monthly_income = int(input())
print("Enter the interest rate of the bank for your savings:")
interest_rate = float(input())
print("Enter the values for your expenses:")
input("Press Enter to continue...")
print("Enter your monthly rent or electricity bill:")
electricity = int(input())
print("Enter your monthly food expenses:")
food = int(input())
print("Enter your vehicle expenses:")
vehicles = int(input())
print("Enter your mobile and internet expenses:")
mobile_internet = int(input())
print("Enter your local expenses:")
local = int(input())
print("Enter your other expenses:")
other = int(input())
```

- **Monthly income:** User enters their monthly income.
- **Bank interest rate:** User provides the bank interest rate for savings.
- **Expense categories:**
 - Rent/Electricity
 - Food
 - Vehicle
 - Mobile & Internet
 - Local expenses
 - Other expenses

2. Calculating Expenses and Savings

```
total_expenses = electricity + food + vehicles + mobile_internet + local + other
savings = monthly_income - total_expenses
```

- Total expenses are computed by summing all the inputted expense categories.
- Savings are calculated as the difference between monthly income and total expenses.

3. Displaying Monthly and Yearly Summary

```
display_header("Your Expenses and Savings")
print("Your total expenses are:", total_expenses)
print("Your savings are:", savings)
```

- Total monthly expenses and savings are displayed.
- Yearly expenses for each category and total yearly savings are calculated and presented.

4. Additional Functionalities

```
input("press enter -----")
print("Enter 1 to calculate savings over multiple years:\nEnter 2 to see percentage of expense")
display_header("")
choice = int(input("enter the choice"))
if choice == 1:
    print("For how many years do you want to see your savings?")
    years = int(input())
    total_savings = yearly_savings
    total_interest = 0

    for _ in range(years):
        interest_earned = (interest_rate / 100) * total_savings
        total_savings += interest_earned
        total_interest += interest_earned

    print("Your total savings after", years, "years will be:", total_savings)
    print("Total interest earned:", total_interest)
```

Choice 1: Savings Over Multiple Years

- The user can input the number of years to see savings growth with interest.
- Interest is compounded yearly.
- Displays the total savings and interest earned after the specified years.

Choice 2: Expense Percentage Breakdown

- The program calculates the percentage of each expense category relative to the user's monthly income.
- Displays the percentage for each category and the total expense percentage

This project serves as a basic yet functional expense and savings tracker, demonstrating core programming concepts such as loops, conditionals, and user input handling in Python.

You can run this program in any compiler like python idle ,vs code PyCharm etc
